Classification

Capgemini

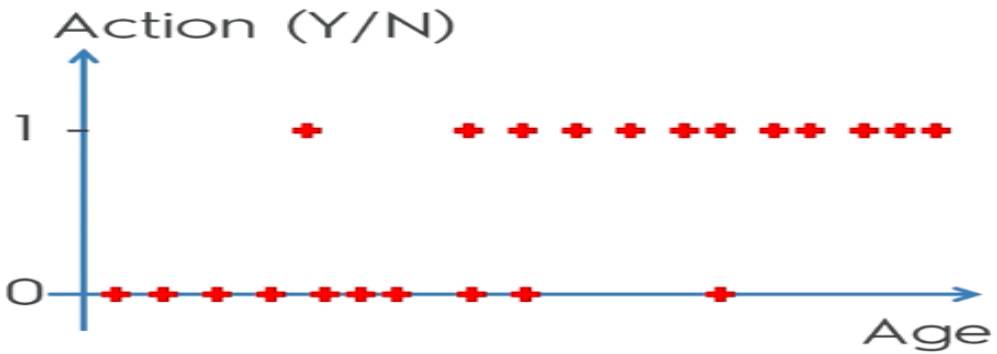
Lesson Objectives

On completion of this lesson, you will be able to understand :

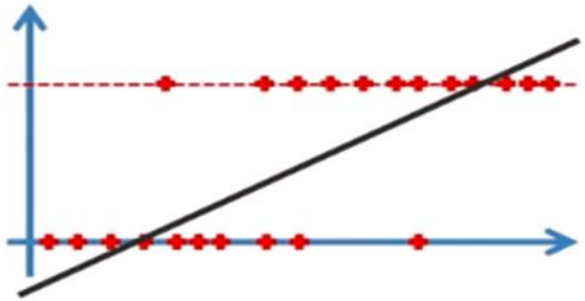
- The key-steps of how to create a Logistic-Regression Model for Classification :
- Train the Model
- Test the Model

Classification

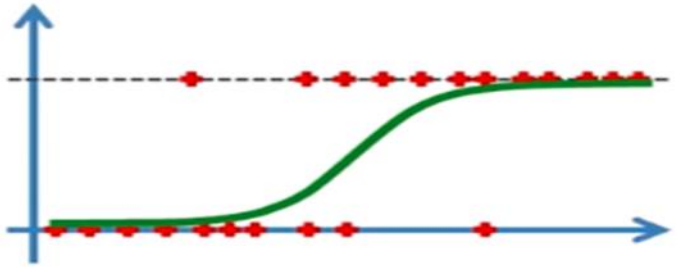
- In classification you predict a category of an Observation
- Classification models are a type of Supervised-Learning
- Classification models include Logistic Regression, SVM, K-NN, Kernel SVM and Random Forests
- Example would be to predict whether a customer would buy or NOT buy a particular product



- Why Logistic Regression and why not Linear Regression?

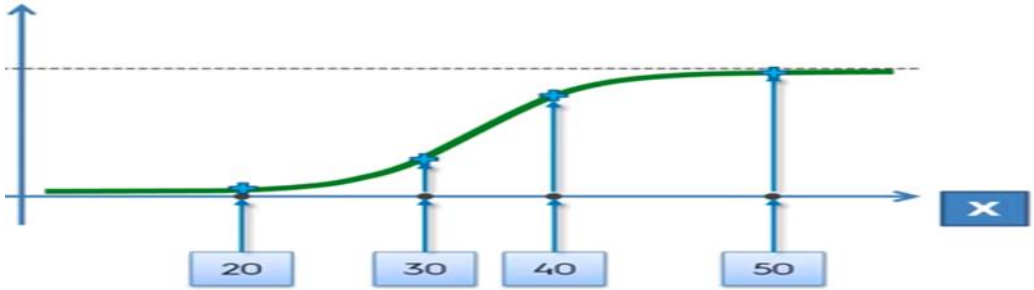


Linear Regression

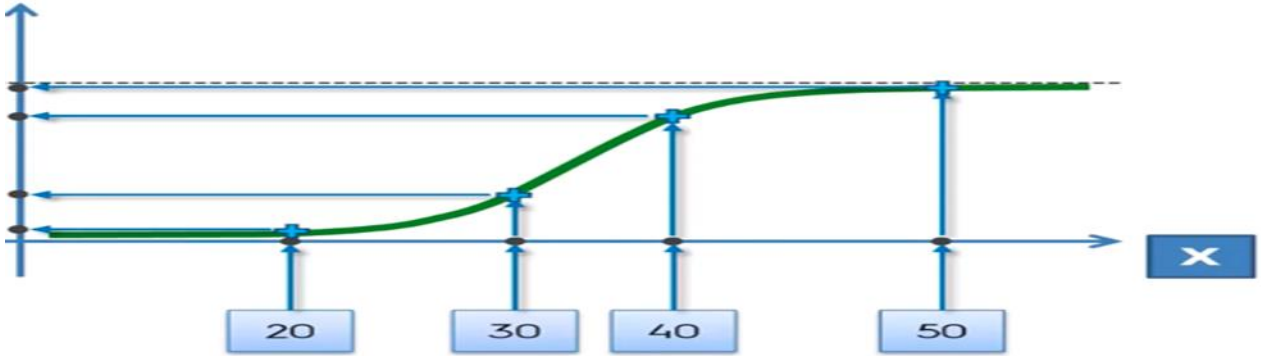


Logistic Regression

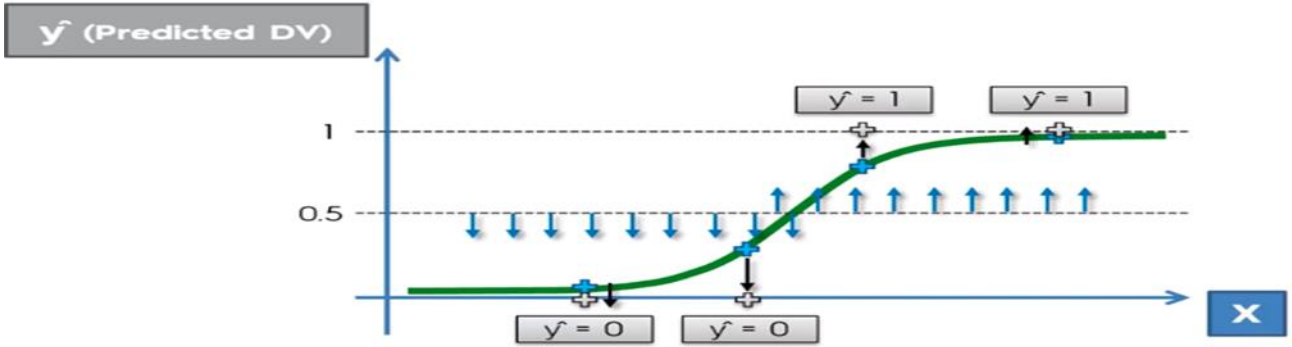
- Using Logistic Regression curve



- Plotting the values on the Y-axis



- How to predict



- Change the directory to the path where our data-set lies “C:\BigData\MachineLearning\Machine Learning A-Z Template Folder\Part 3 - Classification\Section 14 - Logistic Regression”

- In a new file in Spyder, paste the template-file code

- Import the basic libraries

```
#Importing the libraries
import numpy as np
import matplotlib.pyplot as plt
import pandas as pd
```

- Import the Dataset

```
# Importing the dataset
dataset = pd.read_csv('Social_Network_Ads.csv')
```

- Create the matrix of Independent Variables(IVs)

```
x = dataset.iloc[:,[2,3]].values
```

- Create the vector of Dependent Variable(DV)

```
y = dataset.iloc[:,4].values
```

- Check the values of “x” and “y”

Splitting the Data into Training-set and Test-set

- Import the train_test_split function from the library sklearn.model_selection :

```
# Splitting the Data into Training-set and Test-set
from sklearn.cross_validation import train_test_split
or
from sklearn.model_selection import train_test_split
```

- Create 4 variables : x_train, x_test, y_train, y_test as follows :

```
x_train, x_test, y_train, y_test = train_test_split(x,y, test_size = 0.25, random_state= 0)
```

- Our training-sets : x_train(as training data from the matrix of features of independent variables)and y_train(as training data from the vector of dependent variables associated with x_train)

- Our test-sets : x_test(as test-data from the matrix of features of independent variables) and y_test(as test-data from the vector of dependent variables associated with x_test)

Feature Scaling

- To prevent any IV from the matrix of IVs from dominating the entire ANN architecture, we need to implement feature-scaling

```
#Feature scaling the Data
from sklearn.preprocessing import StandardScaler
sc = StandardScaler()
x_train = sc.fit_transform(x_train)
x_test = sc.transform(x_test)
```

Fitting the Logistic Regression

- Importing the Logistic Regression Class

  ```
  from sklearn.linear_model import LogisticRegression
  ```

- Create an object for the Logistic-Regression Model

  ```
  classifier = LogisticRegression()
  ```

- Fit the Logistic-Regression Object to the Training-set

  ```
  classifier.fit(x_train, y_train)
  ```

Testing the Logistic Regression Model

- Test the model on the Test-dataset

```
#Predictions on the Test-set
y_pred = classifier.predict(x_test)
```

- Check and Compare the values of the variables y_pred and y_test

- Using the Confusion-Matrix function to check the accuracy of the predictions

N=200	Predicted FALSE	Predicted TRUE
Actual FALSE	100	12
Actual TRUE	13	75
Percentage of Accuracy (100+75)/200		0.875

- Import the function to create the Confusion Matrix

```
# Making the Confusion Matrix
from sklearn.metrics import confusion_matrix
```

- Create an object to implement the Confusion Matrix for our data

```
cm = confusion_matrix(y_test, y_pred)
```

- Check the value of the "cm" variable

	0	1
0	65	3
1	8	24

N=100	Predicted False	Predicted True
Actual False	65	3
Actual True	8	24

Thank You
